**Keywords:** Bobtail squid, *Euprymna hyllebergi*, Persian Gulf

The family Sepiolidae comprises over 50 species in 14 genera. They are commonly known as bobtail squids with a worldwide distribution from tropical to temperate and sub-polar latitudes of all oceans (Nateewathana, 1997; Aungtonya *et al*., 2011).

*Euprymna hyllebergi* belongs to the Sepiolidae family and Sepiolinae subfamily. This species has a wide distribution in the Eastern Indian Ocean, and has been recorded up to the depth of 47 meters in Andaman Sea, Thailand (Jereb and Roper, 2005). The family Sepiolidae, includes all bobtail squids with kidney-shape fins little is known about their biology, but they are common in tropical, temperate and sub polar waters of all oceans (Jereb and Roper, 2010). This is the first record of the bobtail squid, *E. hyllebergi* from the Persian Gulf. On 27th of March 2013 during a Scuba diving session in Persian Gulf (Figure 1, coordinates: 54° 49'39.5"E, 26° 26' 55.3"N) about 200 eggs of *E.hyllebergi* were collected at the depth of 40 meters in northern Persian Gulf. The eggs (Fig. 2a) were transferred to the Persian Gulf Shellfishes Research Center laboratory for further incubation and hatching. The eggs were lemon shape, 2.5 to 4.0 mm in diameter, pale brown and gathered in
The first record of bobtail squid, *Euprymna hyllebergi*, was not included in the list of Cephalopods reported from the Persian Gulf basin (Valinassab, 1993; Jereb and Roper, 2005). Morphometric characteristics of two specimens of *E. hyllebergi* (13.4 and 11.9 mm Mantle Length) are presented in Table 1.

**Figure 1:** Map of sampling location in the northern Persian Gulf.

**Table 1:** Morphometric characteristics of two *E. hyllebergi* specimens in the Persian Gulf with a comparison with available literature.

Morphometric measurements in these specimens are consistent with those in studies of Nateewathana (1997), Nateewathana et al. (2001) and Aungtonya et al. (2011). Mantle is short and rounded, dorsal mantle fused to head. Fins are short, arms are thick and short, and arm suckers are tetraserial. Tentacular club suckers indistinct and hardly visible. Cuttlebone, in dorsal mantle is wide and synthesizes CaCO₃. Studies in the laboratory indicated that E. hyllebergi grow and mature within 100 to 140 days following hatching. E. hyllebergi is a semelparous species and has a short life cycle (Unpublished data).
