**Keywords:** Southern ocean sunfish, *Mola ramsayi*, Oman Sea, Iran

This report provides the first record of the *Mola ramsayi* from the northern Oman Sea, Iranian waters. The order Tetradontiformes contain the Molidae family that is a diverse marine fish group and contains eight families, 64 genera, and 320 species (Nelson, 2010). Ocean sunfish or molas belong to the family Molidae. These species are epipelagic in nature (Matsuura, 2002). The molid species are characterized in having a distinctive laterally compressed shape, two fused teeth in jaws, no spines in dorsal and anal fins, no caudal peduncle; caudal fin lost; posterior and end of body reduced to a leathery flap or pseudo-caudal (clavus). Johns and Britz (2005) tested the hypothesis that the clavus is 1) a highly modified caudal fin, or 2) formed by highly modified elements of the dorsal and anal fins. Based on ontogenetic elements, they concluded that the later is correct, that is formed by modified elements of the dorsal and anal fin, and that the caudal fin is lost in molids. Jawad et al. (2010) provide a literature review on Molidae family in which goes back to the earliest descriptions by Linnaeus (1758) and by Koelreuter (1766). Since then, 19 genera and 54 species of sunfish have been proposed (Parenti, 2003). The comprehensive taxonomic revision of the family is that of Fraser-Brunner (1951) in which he distinguished five species in three genera: *Ranzania laevis, Masturus oxyuropterus, Masturus lanceolatus, Mola mola* and *Mola ramsayi*. At present, according to Nelson (2010) there are four recognized species (excluding *Masturus oxyuropterus*).
The previous reported on distribution pattern of *M. ramsayi* is in the southern oceans, south-west Pacific: Australia and New Zealand, south-east Pacific: Chile and south-east Atlantic: South Africa. Al-Ghais (1994) recorded this species from the United Arab Emirates waters and the last record was reported from the southern waters of the Oman Sea, Sultanate of Oman by Jawad et al. (2012). In the present study, we record *M. ramsayi* for the first time from the northern Oman Sea, Iranian waters; and it is the fourth record for this species from the northern hemisphere and the third for the Oman Sea as the study area. The Oman Sea with an area of 94000 km², and a depth reaching 3200 m, connects the Persian Gulf to the Indian Ocean through the Arabian Sea. The Oman Sea is in the subtropical zone lying almost entirely between the latitudes of 24° and 30°N and longitudes of 56° 30' to 61° 25'E (Valinssab et al., 2006).

A single 145 cm total length, and weight 156 kg specimen of *M. ramsayi* (Fig. 1) was found at a depth of 85m on the coasts of Jask Port, 400 km east of the Bandar Abbass, center of the Hormuzgan province in the northern Oman Sea, Iran (Fig. 2) during a midwater trawl survey in June 2012.

The geographical position of sampling area was 57° 31' E / 25° 31'N, about 17 nautical miles offshore.
There are two species in the genus *Mola* consist of *Mola ramsayi* and *Mola mola*. Occurrence of sunfishes in the Persian Gulf and Oman Sea are few in the past three decades (Asadi and Dehghani, 1986; Al-Ghais, 1994; Al-Baz et al., 1999; Jawad et al., 2010, 2011, 2012). The most dominant and occurrence species in the Oman Sea and the Persian Gulf (as other connected water body to the Oman Sea) is *Mola mola* but the other identified species, namely *Mola ramsayi* and *Ranzania laevis* have been observed rarely only for very few specimens (3-4 specimens) up to now. Morphometric and meristic data is tabulated in Table 1 and compared with those few specimens caught off United Arab Emirates, southern Oman Sea, India, and Chile.

NA: not available

We would express our sincere gratitude to Professor Randall to confirm the species identification. The authors would also like to thank M. Deldar, fisherman of fishing vessel for his cooperation for delivering the sunfish specimen.
